DNA genetic sequences vary considerably between individuals. These changes are collectively called DNA variants. Most DNA variants have little apparent functional significance, in which case they are known as DNA polymorphisms. By convention, a polymorphism is a difference in DNA

DNA polymorphisms are the different DNA sequences among individuals, groups, or populations. Polymorphism at the DNA level includes a wide range of variations from single base pair change, many base pairs, and repeated sequences.

A general definition of genetic polymorphism is that the locus (or the genetic entity under consideration) should contain two or more alleles, with the most common allele having a frequency of 99% or less. A more stringent definition of genetic polymorphism sets a lower limit to the frequency of the most common allele (95% or less).

Classes of DNA Polymorphisms: ADVERTISEMENTS: There are some major classes of DNA polymorphisms. They are: 1. Single Nucleotide Polymorphisms: SNP is a single base pair change, a point mutation, and the site is referred to as SNP locus. SNPs are the most common type of DNA polymorphism, occurring with a frequency of one in 350 base pairs, and ...

The surveys have yielded four important observations about DNA sequence diversity. First, diversity varies among species; for example, *Drosophila melanogaster* (*drosophila*) is  $\approx 8$ - to 13-fold more diverse at the DNA sequence level than humans (3). Second, the effects of natural selection and demography vary among species.

Presently, geneticists use the term genetic polymorphism to describe the inter-individual, functionally silent differences in DNA sequence that make each human genome unique. [14] Genetic polymorphism is actively and steadily maintained in populations by natural selection, in contrast to transient polymorphisms where a form is progressively replaced by another.

In this study, the Y was systematically surveyed for further long-range polymorphisms, by the hybridization of 33 probes to Sfi digests of DNA from males of different ethnic origins and from the two groups. Five novel polymorphisms were identified, all showing variability consistent with a changing number of tandem repeats within an array.

Single nucleotide polymorphisms (SNPs) are a single nucleotide changes that happen in the genome in a particular location. The single nucleotide polymorphism is the most common form of genetic variation. Small-scale insertions/deletions (Indels) consist of insertions or deletions of bases in DNA.

To detect the polymorphism and a per- son's genotype, one performed assays for the gene product, i.e., the protein or enzyme produced by the genetic blueprint. Most of these polymorphisms were detected in blood. When your blood is typed, you are informed that you are blood group O+ or AB- or A+, etc.
