Classical thermodynamics is based on the four laws of thermodynamics. In thermodynamics we are concerned with the behavior of vast quantities of particles in the substances that we study. The laws of thermodynamics are the laws of the generalized behavior of the particles. These laws are as follows:

In classical thermodynamics dealing with the volume work, two types of heat capacity are distinguished: C_V and C_p . The specific heat c_V [$J\ g^{-1}\ K^{-1}$] and the molar heat capacity C_V [$J\ mol^{-1}\ K^{-1}$] are interrelated through $C_V = c_V M_r$, where M_r is the molar mass. The difference between C_V and C_p for solids is.

The classical version of statistical mechanics, in which we divide up phase-space into cells of equal volume, is valid in this limit. The number of states, $\Omega(E,V)$, lying between the energies E and $E+\delta E$ is simply equal to the number of cells in phase-space contained between these energies.

In classical thermodynamics, the second law of thermodynamics is usually rationalized by considering processes involving the conversion of work to heat by engines that return to their original thermodynamic state after one cycle. Comparison is made to a hypothetical engine, known as a Carnot engine, which is imagined to execute a reversible cycle.
