A Laplace-transform analytic element method (LT-AEM) is described for the solution of transient flow problems in porous media. Following Laplace transformation of the original flow problem, the analytic element method (AEM) is used to solve the resultant time-independent modified Helmholtz equation, and the solution is inverted numerically back into the time domain.

When searching for the solution of a differential equation using the Laplace Transform, derivatives of the unknown and sought-for signal  $f(t)$  are replaced by algebraic quantities proportional to some power of the frequency variable  $s$  times  $F(s)$  or some power of  $s$  multiplying the initial conditions  $f(0)$ ,  $f'(0)$ , and so on.

The Laplace transform can be alternatively defined as the bilateral Laplace transform, or two-sided Laplace transform, by extending the limits of integration to be the entire real axis. If that is done, the common unilateral transform simply becomes a special case of the bilateral transform, where the definition of the function being transformed is multiplied by the Heaviside step function .

The Laplace transform is an integral transform that is widely used to solve linear differential equations with constant coefficients. When such a differential equation is transformed into Laplace space, the result is an algebraic equation, which is much easier to solve.
