Two kinds of the engines which have been recently recognized as low noise and vibration engines are chosen in this study. The cylinder blocks of the engines are called of long skirt type and ladder frame type, respectively. The vibration characteristics of these cylinder blocks are obtained in the frequency range from 500 Hz to 2 kHz using the experimental modal analysis. This frequency range is chosen in consideration of the reliability of the vibration experiments.

Experimental Study of the Correlation Between Crankshaft Vibrations, Engine-Structure Vibrations, and Engine Noise in High Speed Engines. 951290. In most high-speed engines, the crankshaft systems can become one of the most dangerous excitation sources. Since the crankshaft has significant kinetic and elastic (potential) energy, and is subjected directly to the impulsive excitation forces, significant engine structure noise and vibrations can often be caused.
